Random walk, in probability theory, a process for determining the probable location of a point subject to random motions, given the probabilities (the same at each step) of moving some distance in some direction. Random walks are an example of Markov processes, in which future behaviour is independent of past history.

Brownian motion of particles, stock ticker movement, living cell movement in a substrate are just some of the better known random walks seen in real world. Here, we simulate a simplified random walk in 1-D, 2-D and 3-D starting at origin and a discrete step size chosen from $[-1, 0, 1]$ with equal probability.

The random walk is a somewhat popular mathematical construct that is used in computer science, and now in machine learning. It is described as a "stochastic" process because it works through the application of random variables. The random walk essentially tracks incremental steps by a particular modeled intelligence or digital "rational actor."
