In multiple linear regression, the  $R^2$  represents the correlation coefficient between the observed values of the outcome variable ( $y$ ) and the fitted (i.e., predicted) values of  $y$ . For this reason, the value of  $R$  will always be positive and will range from zero to one.

A multiple R-squared of 1 indicates a perfect linear relationship while a multiple R-squared of 0 indicates no linear relationship whatsoever. Multiple R is also the square root of R-squared, which is the proportion of the variance in the response variable that can be explained by the predictor variables.

In R, multiple linear regression is only a small step away from simple linear regression. In fact, the same `lm()` function can be used for this technique, but with the addition of a one or more predictors. This tutorial will explore how R can be used to perform multiple linear regression.

In other words,  $R^2$  always increases (or stays the same) as more predictors are added to a multiple linear regression model, even if the predictors added are unrelated to the response variable. Thus, by itself,  $R^2$  cannot be used to help us identify which predictors should be included in a model and which should be excluded.

Multiple Linear Regression This is the regression where the output variable is a function of a multiple-input variable.  $y = c_0 + c_1*x_1 + c_2*x_2$  In both the above cases  $c_0$ ,  $c_1$ ,  $c_2$  are the coefficient's which represents regression weights.
